**Supplemental figure.** Determination of regular (R-) and wave (W-) type RT. After processing of the pseudo-color images using ImageJ, colors were split into 3 channels including red, green, and blue images (8 bit). Each image was adjusted based on threshold, and three binary images were produced for each pseudo-color image. The boundary of the black and white area in each binary image was used when determining R- or W-type RT. W-type was assigned when the amplitude of the wave of the boundary on the split images exceeded 1500 microns. R-type was assigned when the amplitude of the wave was 1500 microns or less.
