

Supplementary Figure legend

Figure S1. Control rat IgG treatment alone does not affect the ear thickness with the negative control.

C57BL/6 spleen cells were injected into the right ear pinna of normal BALB/c mice, and specific ear swelling was measured 24 h later as negative control. The mice were treated with rat IgG or no treatment as negative control for 1 day. The figure shows the results of an experiment with mice treated with no treatment or rat IgG as a negative control (n = 6 per group, N.S.: not significant). Data were analyzed using the two-tailed Student's t test.
