Supplemental Figure 1: Immunocytochemistry (ICC) of IE antigen in CMV-infected human corneal endothelial cells (hCECs). The upper panels show cells that were stained with 4′,6-diamidino-2-phenylindole (DAPI). The middle panels show cells stained for the IE antigen. The lower panels show merged images. The expression data for mock infection are shown in the left row; the expression data after 1 day of infection are in the right row. The IE antigen was expressed at 24 h postinfection. Bar: 200 µm.
